The Department of Energy will provide public access to these results of federally sponsored research in accordance with the DOE Public Access Plan.

# Problem Statement

Complex characteristics (anisotropic, non-spherical) of wood must be considered to accurately predict biomass pyrolysis.

Devolatilization of biomass particles requires sufficient heat up time to produce optimal product yields.

Microscopy of biomass feedstocks. Source: Peter Ciesielski, NREL.

SEM micrographs of real biomass particles.  
Source: Peter Ciesielski, NREL.

Anisotropic and heterogeneous properties of wood are often not accounted for in low-order models.

[Chaurasia 2003, Babu 2004, Gronli 2000, Haseli 2011, Koufopoulos 1991, Kung 1972, Larfeldt 2000, Okekunle 2011, Papadikis 2010, Prakash 2009, Pyle 1984, Sadhukhan 2009]

Reactor models often ignore temperature gradients within large biomass particles.

[Cui 2007, Souza-Santos 2010]

Most pyrolysis models treat wood particles as “one” size, ignoring particle size distributions from wood grinders and mills.

[Di Blasi 2002, Bryden 2002, Chaurasia 2003, Cui 2007, Galgano 2003, Galgano 2004, Gronli 2000, Haseli 2011, Janse 2000, Koufopoulos 1991, Kung 1972, Larfeldt 2000, Miao 2011, Papadikis 2009]

1-D models in literature frequently validate with experimental data for particle sizes  $> 6$  mm, whereas typical size for fast pyrolysis in fluidized bed reactors is  $< 6$  mm.

[Chan 1985, Di Blasi 2003, Bridgwater 2012, Galgano 2006, Gaston 2011, Gronli 2000, Koufopoulos 1991, Meier 2013, Pyle 1984, Rath 2002, Sadhukhan 2009, Trendewicz 2014]

Accurately predict the pyrolysis of a biomass particle without using expensive HPC resources.

Use detailed 3-D microstructure models (NREL) to validate and improve low-order particle models for heat transfer in biomass particles at fast pyrolysis conditions.

Account for effects of particle size distribution and shape on heat up time of biomass particles.

# Realistic 3-D particle models with microstructure

5

Detailed microscopy providing highly resolved species-specific microstructure.

Allows assessment of microstructure on heat/mass transfer during pyrolysis.

Enables simulations of oil yield and composition at the particle scale as functions of feedstock species, particle size distribution, and moisture.

FEM simulation of accurately shaped model with bulk thermal properties

≈?

Low order/1-D heat transfer model appropriate shape descriptors and thermal properties

# Low-order particle model

Approximate heat-up as 1-D conduction with bulk properties and simple boundary conditions.

$$\rho C_p \frac{\partial T}{\partial t} = \frac{1}{r^b} \frac{\partial}{\partial r} \left( k r^b \frac{\partial T}{\partial r} \right) + g \quad \text{intra-particle heat conduction}$$

$$k \frac{\partial T}{\partial r} \bigg|_{r=R} = h(T_\infty - T_R) \quad \text{boundary condition with convection at particle surface}$$

$$\frac{\partial T}{\partial r} \bigg|_{r=0} = 0 \quad \text{boundary condition with symmetry at particle center}$$

Where

$\rho$  = density (kg/m<sup>3</sup>)

$C_p$  = heat capacity (J / kg·K)

$k$  = thermal conductivity (W / m·K)

$T$  = temperature (K)

$T_\infty$  = ambient temperature (K)

$T_R$  = surface temperature (K)

$r$  = radius (m)

$b$  = shape factor of 0=slab, 1=cylinder, 2=sphere

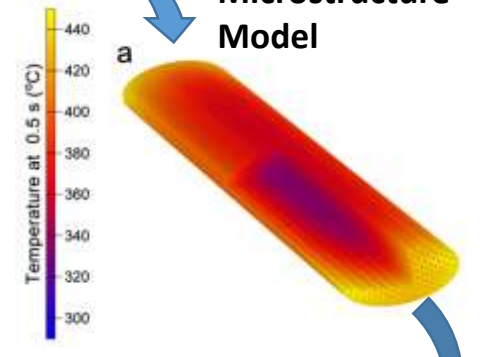

$g$  = heat generation (W/m<sup>3</sup>)

$h$  = heat transfer coefficient (W / m<sup>2</sup>·K)

SEM image of wood particle

Microstructure Model

Low-Order Model

# Characterizing irregular shaped particles

9

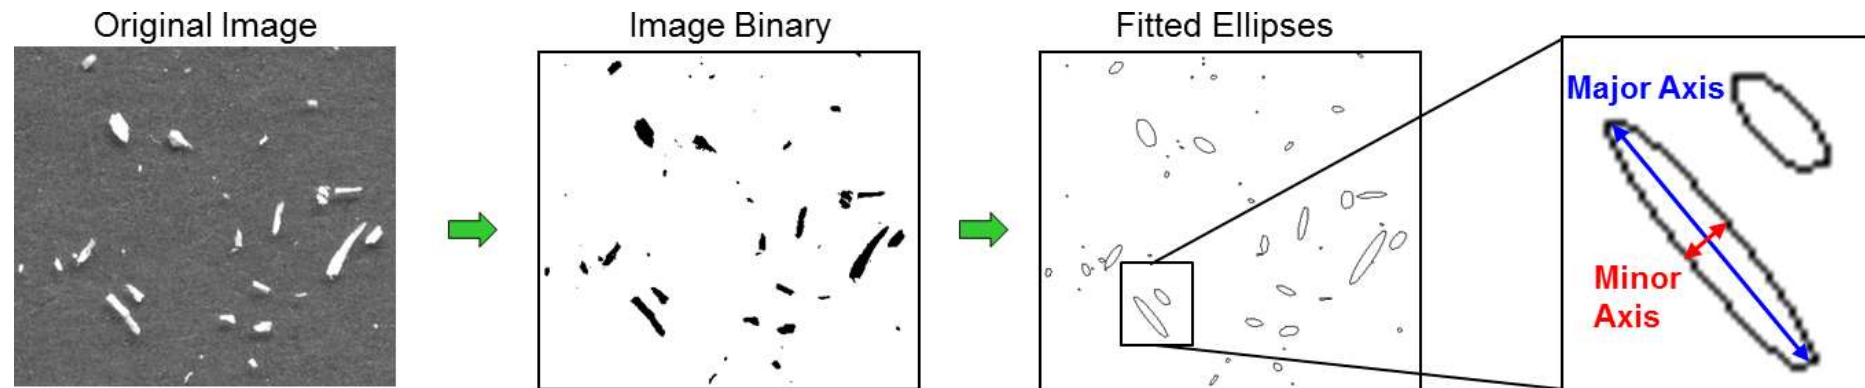

An equivalent diameter or characteristic length can be used to represent a measured parameter (surface area, volume, etc.) of an irregularly shaped particle.

# Particle size distribution determined from image analysis<sup>10</sup>

Particles classified into regimes based on Feret diameter by image analysis of 0.5 mm and 2.0 mm sieve samples.

Feret diameter ( $D_F$ ) is the longest distance between two points on a two-dimensional plane.

Source: Peter Ciesielski, NREL.

More details about particle characterization provided in microstructure paper.<sup>[1]</sup>

# Dsv model reproduces 3-D temperature profiles

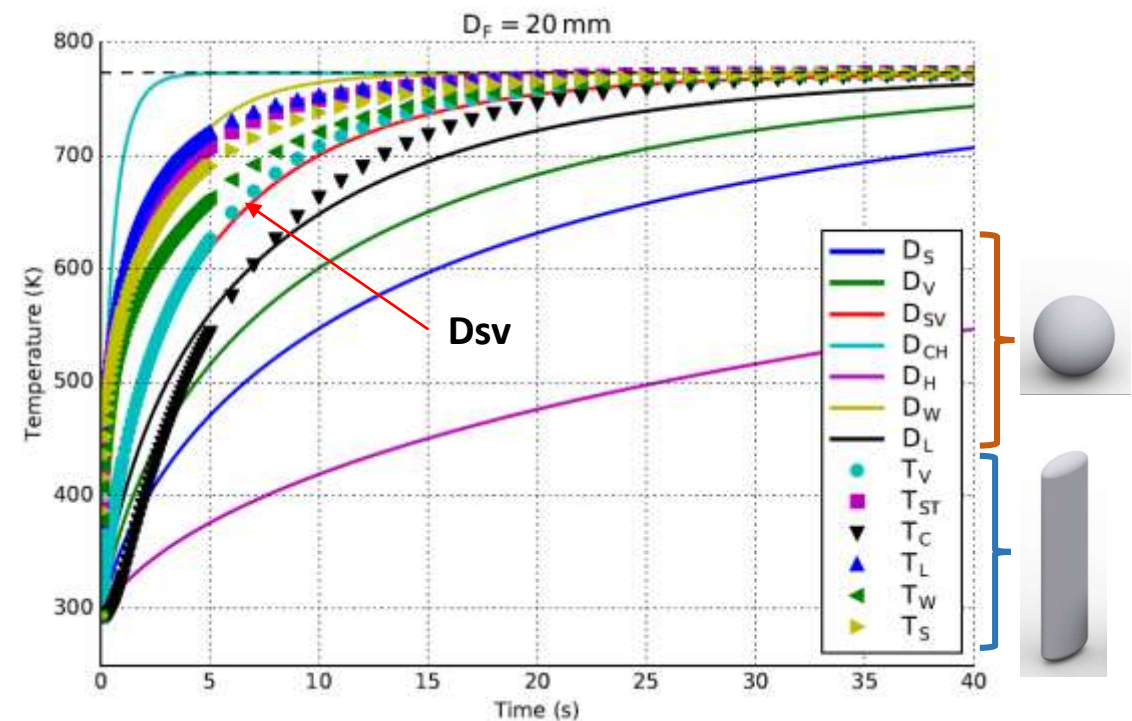

Bulk properties from Wood Handbook used for 3-D and 1-D particle model comparison for pure heat conduction (no kinetics).

Property	Loblolly Pine	White Oak
$\rho$ (kg/m <sup>3</sup> )	540	720
$k$ (W/m·K)	0.12	0.16
$h$ (W/m <sup>2</sup> ·K)	350	350
$C_p$ (J/kg·K)	$103.1 + 3.867 T$	$103.1 + 3.867 T$
$T_o$ (K)	293	293
$T_f$ (K)	773	773

Geometry for calculating equivalent diameters.

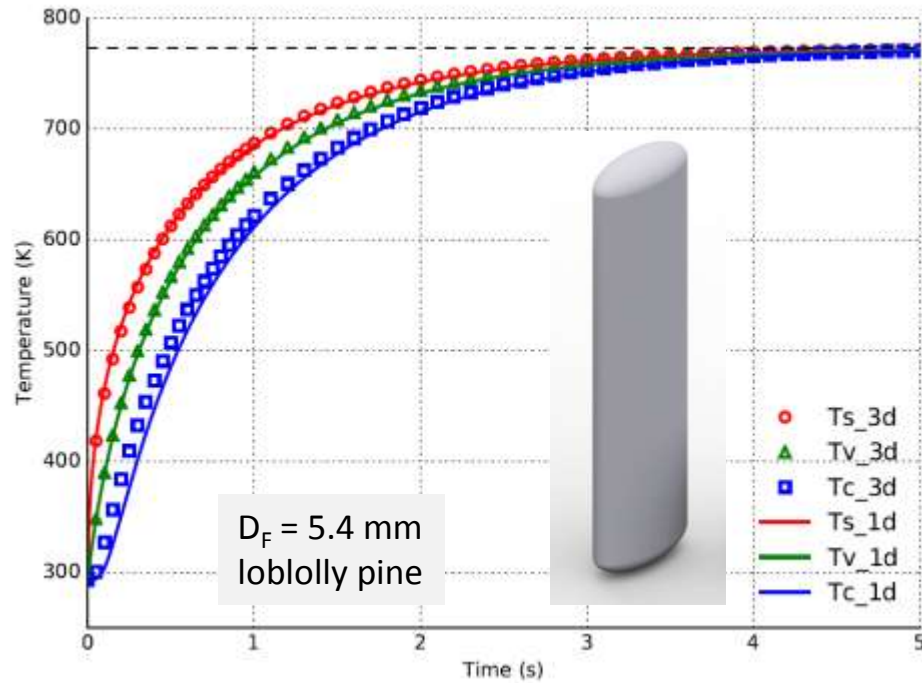

Locations of temperature profiles.

Source: [2].

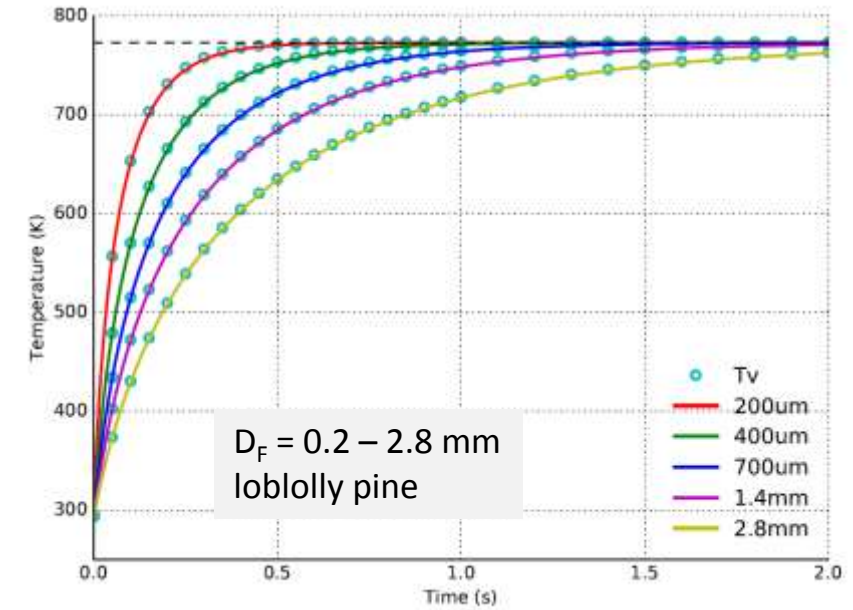

# Dsv model reproduces 3-D temperature profiles

Low-order Dsv model capable of reproducing surface ( $T_s$ ), center ( $T_c$ ), and volume average ( $T_v$ ) temperature profiles of 3-D particle model.

Volume average temperature of low-order Dsv particle model matches 3-D results for a range of particle sizes.

Source: [2].

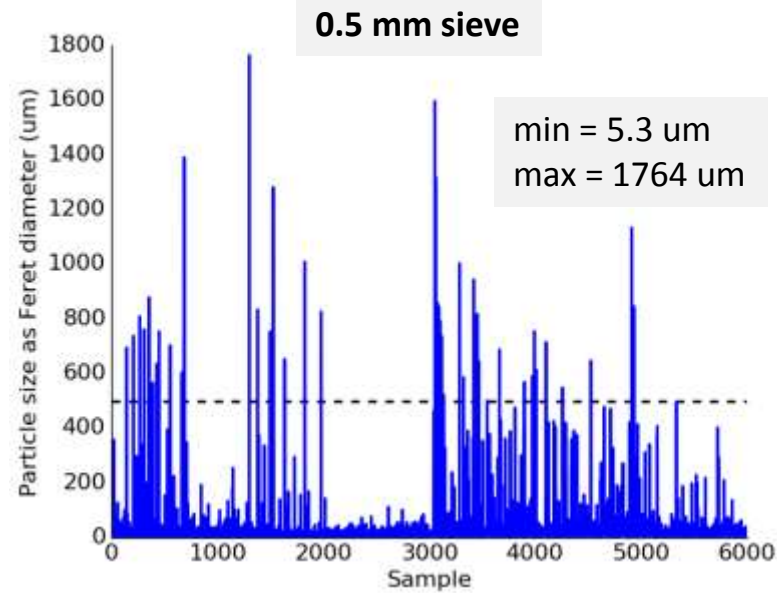

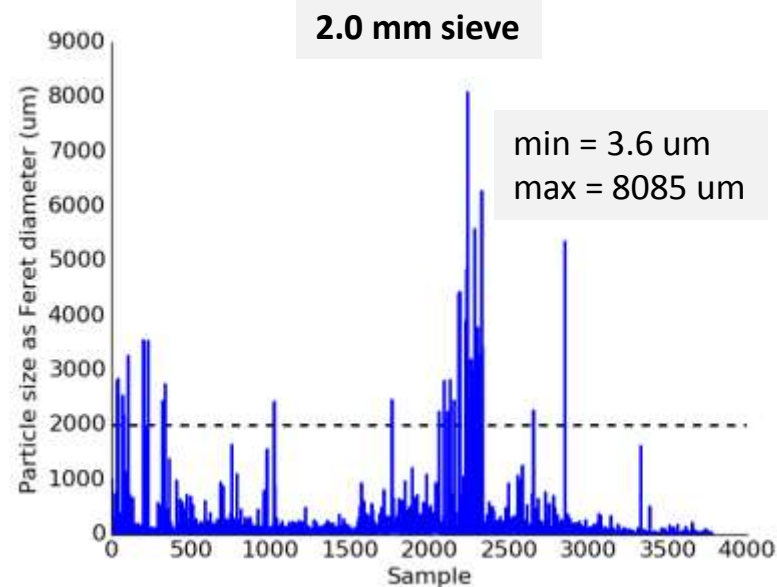

# Biomass feedstock contains a range of particle sizes

13

Raw data from image analysis

Particle size distribution from image analysis

# Particle characterization affects temperature profile

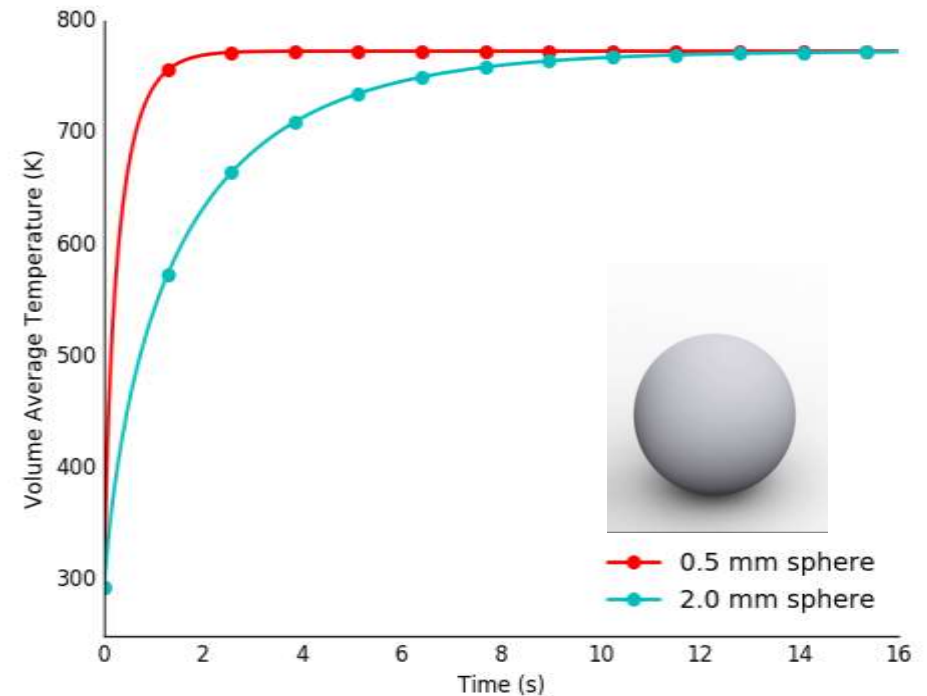

Low-order Dsv model utilizing bulk thermal properties for loblolly pine was applied to each particle size.

Assuming biomass feedstock is same sphere size as sieve produces misleading results.

Temperature profiles from low-order model for with  $D_F = 81 - 5277 \text{ } \mu\text{m}$  and single sphere with  $D = 0.5$  and  $2 \text{ mm}$ .

Temperature profiles from low-order model for solid sphere.

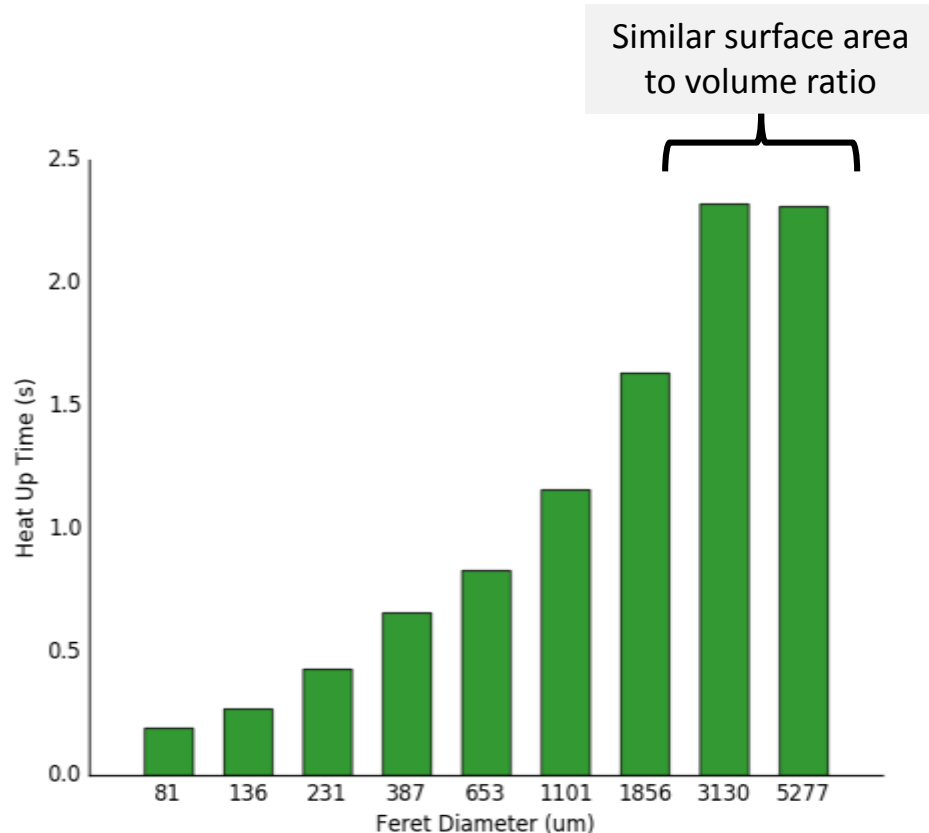

# Particle size distribution affects overall heat up time

15

Volume fraction of each bin used to calculate contribution to heat up time.

Accounting for entire range of particle sizes in biomass feedstock drastically affects predicted heat up time.

# Reactor models must account for size distributions

Experimental data from 2-inch diameter bubbling fluidized bed reactor at NREL.

Initial model results from Dsv particle model coupled to a low-order reactor model.

- Computational models can provide information about pyrolysis conditions within small particles (very difficult in experiments)
- Sieve/mesh/screen size is not an appropriate dimension to characterize biomass particles
- Particle size and shape distributions must be accounted for to accurately predict heat up time of biomass feedstocks
- Unique shapes (aspect ratio) can be approximated as an equivalent spherical diameter
- Low-order particle model utilizing  $D_{sv}$  and bulk thermal properties approximates heat conduction in realistic wood particles
